Small angle X-ray scattering (SAXS) is a useful technique for extracting structural information from biological samples in solution. However, the X-ray scattering signal from macromolecules is challenging to measure because of low particle concentrations and high background from solvent. As a result, instrument designs for home laboratories, where X-ray intensities are lower than synchrotrons, require special scrutiny. In particular, collimation design, X-ray source and area detector contribute greatly to improved data quality for home laboratory experiments.

Rigaku Oxford Diffraction's BioSAXS-2000 system is a SAXS instrument for the home lab, which combines 2D Kratky collimation with confocal optics to achieve maximum X-ray flux on the sample without the need for data desmearing. The BioSAXS-2000 uses Rigaku's hybrid photon counting detector (HPC), the HyPix-3000. HPCs are ideal for measuring weak scattering from biological solutions because they combine ultra low noise, high dynamic range and direct detection of X-ray photons. In fact, HPCs are the detector of choice for most SAXS beamlines and modern home laboratory SAXS instruments. Results with the BioSAXS-2000 consistently show that this instrument produces high quality SAXS data in minutes.

The BioSAXS-2000 AUTO package includes automation tools to achieve high-throughput biological SAXS out of the synchrotron and into the home laboratory. The AUTO package consists of a 96-well Automatic Sample Changer (ASC) and an Automatic Analysis Pipeline (AAP) that uses the ATSAS[1] package. The BioSAXS-2000, coupled to a Rigaku rotating anode source and a Rigaku HyPix-3000 hybrid pixel counting detector, collects high quality SAXS data in minutes and the AUTO package makes it possible to load a 96-well plate of samples and come back when all data collection and data processing have finished.
